TOP SECRET

PAGE 2

SUBJECT: Ust'-Kamenogorsk Titanium-Magnesium Combine '

In producing titanium metal the titanium ore must first be processed to eliminate impurities and leave a relatively pure titanium oxide. The incoming ore is treated in the ore processing section (see annotated enclosure) where at least some of the concentration or purification takes place. The exact identification of facilities in this section cannot be determined. The next step in the production that can be identified is chlorination which takes place in the tall chlorination building (annotation 2) which measures 535 by 100 feet.

25X′

The titanium sponge (spalt) from the reactors is next purified to remove either magnesium chloride or sodium chloride depending on the reducing agent used. The purification building could not positively be identified; however, building annotated 12 is identified as the probable pruification building. The building where final melting and casting of titanium metal is done could not be identified.

There are a number of unidentified buildings at this plant. At least one of these will contain electrolytic cells for the regeneration of pure magnesium or sodium which in turn is recycled to retorts to reduce titanium tetrachloride. Other buildings may house equipment for further processing of incoming ore prior to chlorination and equipment for the fabrication of titanium products.

A thermal electric power plant (annotation 3), within the plant area, supplies the large power demands of this industry. The source of cooling water for the power plant was not discernible; however, a probable discharge channel (annotation 5) extends from outside the secured area to the Ul'ba River. The exact function and association of the two large and one small basins (annotation 6) near the river could not be determined.

4. No estimate of production capacity can be made from photo evidence alone. The overall plant appears to be active; the power plant is in operation, a slight trace of fumes were being emitted from the stack associated with the chlorinater building, and two piles of light-toned raw material were present (annotation 13). Total roof cover, not including the two groups of administration buildings, is 920,850 square feet.

5. From evidence observed on photography of further expansi of facilities are planned. The area to the west of the completed reactor buildinks been filled and leveled since 1957. Two buildings are in an early stage of construction in this area (annotation 10). Total roof cover of the buildings under construction when completed will be 104,050 square feet.	.on 25X .ng 25X
